## Summary

The Debye scattering equation, derived in 1915 by Peter Debye, is used to calculate scattering intensities from atomic structures considering the position of each atom in the structure (Debye, 1915; Scardi et al., 2016):

$$I(Q) = \sum_{\nu=1}^N \sum_{\mu=1}^N b_{\nu} b_{\mu} \frac{\sin(Qr_{\nu\mu})}{Qr_{\nu\mu}} \quad (1)$$

In this equation  $Q$  is the momentum transfer of the scattered radiation,  $N$  is the number of atoms in the structure, and  $r_{\nu\mu}$  is the distance between atoms  $\nu$  and  $\mu$ . For X-ray radiation, the atomic form factor,  $b$ , depends strongly on  $Q$  and is usually denoted as  $f(Q)$ , but for neutrons,  $b$  is independent of  $Q$  and referred to as the scattering length. The Debye scattering equation can be used to compute the scattering pattern of any atomic structure and is commonly used to study both crystalline and non-crystalline materials with a range of scattering techniques like powder diffraction (PD), total scattering (TS) with pair distribution function (PDF) analysis, and small-angle scattering (SAS) (Scardi et al., 2016). Although the Debye scattering equation is extremely versatile, the computation of the double sum, which scales  $O(N^2)$ , has limited the practical use of the equation.

With the advancement in computer hardware (Schaller, 1997), analysis of larger structures is now feasible using the Debye scattering equation. Modern central processing units (CPUs), ranging from tens to hundreds of cores offer an opportunity to parallelise computations, significantly enhancing compute efficiency. The same goes for graphics processing units (GPUs), which are designed with multiple cores acting as individual accelerated processing units that can work on different tasks simultaneously. In contrast, CPUs usually have fewer cores optimised for more general-purpose computing. This means that a GPU can execute multiple simple instructions in parallel, while a CPU might handle fewer parallel tasks (Garland et al., 2008). Therefore, GPUs are better suited for calculations such as the Debye scattering equation, where many computations can be performed simultaneously. Taking advantage of such GPU acceleration could yield computational speeds that surpass those of even the most advanced multi-core CPUs; by orders of magnitude. We introduce a GPU-accelerated open-source Python package, named DebyeCalculator, for rapid calculation of the Debye scattering equation from chemical structures represented as .xyz or .cif files. The xyz-format is commonly used in materials chemistry for the description of discrete particles and simply

39 consists of a list of atomic identities and their respective Cartesian coordinates (x, y, and  
40 z). DebyeCalculator can take a crystallographic information file (CIF) and a user-defined  
41 spherical radius as input to generate an .xyz file from which a scattering pattern is calculated.  
42 We further calculate the PDF as described by Egami and Billinge (Egami & Billinge, 2003).  
43 We show that our software can simulate PD, TS, SAS, and PDF data orders of magnitudes  
44 faster than DiffPy-CMI (Juhás et al., 2015). DebyeCalculator is an open-source project that  
45 is readily available through [GitHub](#) and [PyPI](#).

46 Here, we present a high-level overview of the DebyeCalculator class. The GitHub repository  
47 provides more details as well as annotated source code.

```

CLASS `DebyeCalculator`:
    FUNCTION Initialise(parameters...):
        - Set class parameters based on given input or defaults
        - Setup scattering parameters (e.g., Q-values, r-values) and hardware parameters
        - Load atomic form factor coefficients
        - Setup form factor calculation based on radiation type

    FUNCTION gr(structure_path, keep_on_device=False):
        - Load atomic structure from given structure_path
        - Calculate atomic form factors
        - Calculate scattering intensity I(Q) (Debye scattering equation)
        - Compute structure factor S(Q) based on I(Q)
        - Calculate F(Q) based on Q-values and S(Q)
        - Apply modifications if necessary (like dampening and Lorch)
        - Calculate pair distribution function G(r) based on F(Q)
        - Return G(r) either on GPU or CPU

```

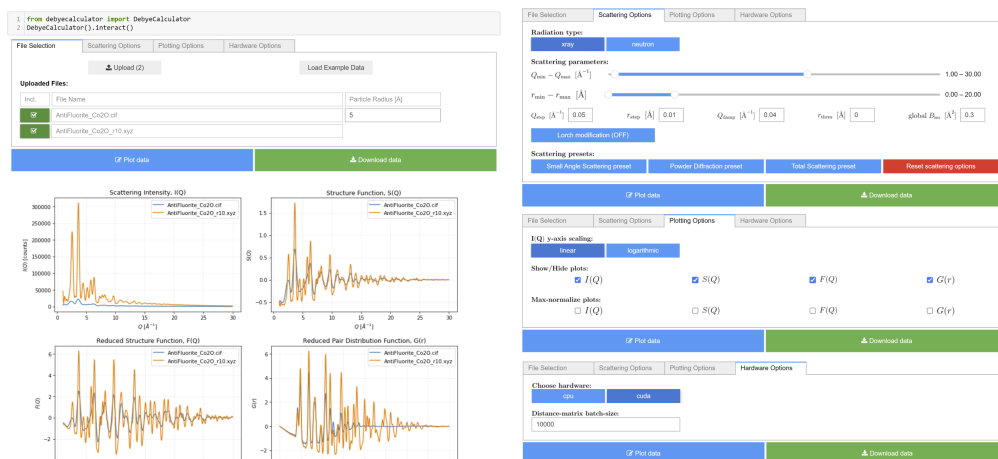

48 In order to benchmark our implementation, we compare simulated scattering patterns from  
49 DebyeCalculator against DiffPy-CMI (Juhás et al., 2015), which is a widely recognised  
50 software for scattering pattern computations. Here, our implementation obtains the same  
51 scattering patterns as DiffPy-CMI (Figure 3), while being faster on CPU for structures up to  
52 ~20,000 atoms (Figure 1). Both calculations are run on a x86-64 CPU with 64GB of memory  
53 and a batch size of 10,000. Running the calculations on the GPU provides another notable  
54 boost in speed (Figure 1). This improvement primarily stems from the distribution of the  
55 double sum calculations across a more extensive set of cores than is feasible on the CPU. With  
56 smaller atomic structures, an overhead associated with initiating GPU calculations results in  
57 the NVIDIA RTX A3000 Laptop GPU computations being slower than DiffPy-CMI and our  
58 CPU implementation. Once the atomic structure size exceeds ~14 Å in diameter (~300 atoms),  
59 we observe a ~5 times speed-up using an NVIDIA RTX A3000 Laptop GPU with 6GB of  
60 memory and a batch size of 10,000. The choice of GPU hardware has a substantial influence  
61 on this speed advantage. As demonstrated in Figure 1, using an NVIDIA Titan RTX GPU,  
62 which offers 24GB of memory, the speed benefits become even more evident. The NVIDIA  
63 Titan RTX GPU delivers a performance that is ~10 times faster, seemingly across all structure  
64 sizes, underlining the significant role of the hardware. With the advancements of GPUs like  
65 NVIDIA's Grace Hopper Superchip (NVIDIA, 2023), which boasts 576GB of fast-access to  
66 memory, there is potential for DebyeCalculator to achieve even greater speeds in the future.

**Figure 1:** Computation-time comparison of the  $G(r)$  calculation using our CPU- and GPU-implementations against DiffPy-CMI (Juhás et al., 2015). For the CPU-implementation, a batch size of 10,000 was chosen (x86-64 CPU with 6GB). Both the GPU implementations were run with a batch size of 10,000 (NVIDIA RTX A3000 Laptop GPU with 6GB of memory and NVIDIA Titan RTX GPU with 24GB of memory). The mean and standard deviation of the PDF simulation times are calculated from 10 runs. Note that, due to limited memory, the Laptop GPU was unable to handle structures larger than ~24,000 atoms. A CIF from an antiferroite structure was used to generate this data.

## Statement of need

Several software packages already exist for simulating the Debye scattering equation, including DiffPy-CMI (Juhás et al., 2015), debyer (Wojdyr, 2023), Debussy (Cervellino et al., 2010, 2015), DISCUS (Th Proffen & Neder, 1999; Thomas Proffen & Neder, 1997), and BCL::SAXS (Putnam et al., 2015). DebyeCalculator stands out as it is open-source, Python-based, and GPU-compatible. Python's status as an extremely popular and accessible language in scientific computing makes it straightforward for researchers to quickly perform Debye scattering calculations while ensuring easy integration with other data science tools. DebyeCalculator is open-source licensed under the Apache License 2.0. Moreover, it can be installed conveniently via `pip install debyecalculator` and has been integrated with Google Colab, allowing users to rapidly calculate PD, TS, SAS, and PDF data using the Debye scattering equation without the need of local software installations. DebyeCalculator can also be run through an interactive interface (see Figure 2), where users can calculate  $I(Q)$ ,  $S(Q)$ ,  $F(Q)$ , and  $G(r)$  from structural models on both CPU and GPU.

**Figure 2:** The interact mode of DebyeCalculator provides a one-click interface, where the user can update parameters and visualise  $I(Q)$ ,  $S(Q)$ ,  $F(Q)$ , and  $G(r)$ . Additionally, the  $I(Q)$ ,  $S(Q)$ ,  $F(Q)$ ,  $G(r)$ , and .xyz file can be downloaded, including metadata.

## Acknowledgements

This work is part of a project that has received funding from the European Research Council (ERC) under the European Union's Horizon 2020 Research and Innovation Programme (grant agreement No. 804066). We are grateful for funding from University of Copenhagen through the Data+ program.

## Supporting Information

**Figure 3:** Comparison of the calculated  $I(Q)$ , SAXS,  $F(Q)$ , and  $G(r)$  of DebyeCalculator and DiffPy-CMI (Juhás et al., 2015) on a discrete, spherical cutout with 6 Å in radius from a  $V_{0.985}Al_{0.015}O_2$  crystal (Ghedira et al., 1977).
